

Yuhan Peng - homework5

December 10, 2023

1 Homework 5 (100 points)

This homework will focus on Neural Networks and visualization.

- a) Write a function that takes a keras network and outputs an image (png format) of the network. (10points)

You can assume the model is sequential and only uses dense layers. The input and output neurons must be blue circles. The hidden neurons must be green circles. The edges must be directed red arrows.

For example, the output image for

```
model = keras.models.Sequential()
model.add(layers.Dense(2, input_dim=2))
model.add(layers.Dense(1))
model.compile(loss="binary_crossentropy")
```

should look exactly like this:

```
[1]: from IPython.display import Image
      Image(filename="example.png")
```

```
[1]:
```

Hint: use the networkx library (specifically the `to_agraph` method)

```
[2]: #libraries used in this exercise
import numpy as np
import networkx as nx
from PIL import Image
import matplotlib.pyplot as plt
from matplotlib.animation import FuncAnimation, PillowWriter

from tensorflow.keras import layers, models
from tensorflow.keras.utils import plot_model
from networkx.drawing.nx_agraph import to_agraph

from IPython.display import Image as img_display
```

```

plt.plot(x_test, y_pred, color='red', label='Fitted Curve')
plt.xlabel('x')
plt.ylabel('y')
plt.title('Neural Network Model Fit')
plt.legend()
plt.show()

```

4/4 [=====] - 0s 1ms/step

Neural Network Architecture Number of Layers and Neurons The model is designed with two hidden layers, each containing 128 neurons. This architecture choice is based on a few considerations:

Complexity of the Function: The underlying function we aim to model is a cubic polynomial, which is inherently more complex than linear relationships. Thus, the model requires sufficient capacity to capture the non-linearities present in the function.

Depth of the Model: While deep learning models benefit from multiple layers due to their ability to learn hierarchical representations, for a single-variable cubic polynomial, it is not necessary to have a very deep network. Two hidden layers are chosen as a balance between model complexity and the risk of overfitting.

Width of the Layers: Each hidden layer is given 128 neurons to allow the model to learn a wide variety of patterns within the data. A higher number of neurons can provide the network with the flexibility to approximate the complex relationship between the input x and the output y .

Activation Function The ReLU (Rectified Linear Unit) activation function is chosen for the following reasons:

Non-linearity: ReLU introduces non-linearity to the model, allowing it to learn complex patterns. This is essential since the relationship we are trying to learn is non-linear.

Computational Efficiency: ReLU is computationally efficient as it simply thresholds values at zero,

which speeds up training without compromising the ability to learn complex patterns.

Vanishing Gradient Problem: ReLU helps mitigate the vanishing gradient problem, especially in networks with many layers, by having a constant gradient for positive input values, which ensures that the weights continue to update during training.

Sparse Activation: ReLU leads to sparse activations; in any given layer, only a subset of neurons is activated, making the network less prone to overfitting.

Output Layer The output layer has a single neuron with no activation function (linear activation by default). This is typical for regression problems where the model predicts a single continuous value. The absence of an activation function means that the network can predict values across the entire range of real numbers, which is appropriate for the given task.

- e) Create an animation of the resulting curve learned by your model throughout the training process. (15points)

```
[15]: import numpy as np
import matplotlib.pyplot as plt
from tensorflow.keras import models, layers, callbacks
from matplotlib.animation import FuncAnimation

# Generate data
np.random.seed(0)
x_data = np.linspace(-10, 10, 100)
e = np.random.normal(0, 1, x_data.shape)
y_data = 5 * x_data**3 + 3 * x_data**2 + x_data - 1 + e

# Prepare a callback to store weights after each epoch
class WeightsLogger(callbacks.Callback):
    def __init__(self):
        self.weights = []

    def on_epoch_end(self, epoch, logs=None):
        # Predict and store the curve
        y_pred = self.model.predict(x_data)
        self.weights.append(y_pred)

weights_logger = WeightsLogger()

# Create a Neural Network model

f) Below is code to create a Generative Adversarial Network (GAN). The goal of the GAN is to generate data that is fake but looks real. A GAN is separated into two networks (a Generator and a Discriminator) that learn from each other through the following steps at each given training epoch:

1. The Generator generates data
2. The Discriminator is trained to learn how to distinguish real data from the fake data that the generator just generated.
3. The Generator is then trained to improve its ability to generate fake data by being informed by the Discriminator's new ability to distinguish real from fake.

Here is some code to train a GAN to generate 2-dimensional data that looks like a multivariate normal with mean (0,0) and covariance defined below.

The code has one major flaw though that will prevent it from ever generating data that looks like the real data. Something is wrong with the architecture of the model (layers, activation etc). Find and fix that flaw and explain your reasoning below. (15points)

```

epochs = 100
batch_size = 128
images = []

# Define the generator model
generator = Sequential()
generator.add(Dense(32, input_dim=gen_input_dim, activation='tanh'))
generator.add(Dense(2, activation='linear')) # Corrected activation to 'linear'

# Define the discriminator model
discriminator = Sequential()
discriminator.add(Dense(16, input_dim=2))
discriminator.add(ReLU()) # Ensured ReLU is correctly used
discriminator.add(Dense(1, activation='sigmoid'))

# Compile the models
generator.compile(loss='mse')
discriminator.compile(loss='binary_crossentropy')

# Define the GAN model
gan = Sequential()
gan.add(generator)
gan.add(discriminator)
gan.compile(loss='binary_crossentropy')

# Define the real data
x_real = np.random.multivariate_normal([0, 0], [[1, 0.5], [0.5, 1]], 1000)

# Train the GAN
```

```

# don't change the code below
for epoch in range(epochs):
    # Generate fake data
    z = np.random.normal(size=(batch_size, gen_input_dim))
    x_fake = generator.predict(z)

    # Train the discriminator
    discriminator.trainable = True
    discriminator.train_on_batch(x_real, np.ones((len(x_real), 1)))
    discriminator.train_on_batch(x_fake, np.zeros((batch_size, 1)))

    # Train the generator
    discriminator.trainable = False
    gan.train_on_batch(z, np.ones((batch_size, 1)))

```

The Generative Adversarial Network (GAN) architecture provided in the question has a critical issue in the generator's output layer that would prevent it from generating data that resembles a multivariate normal distribution. The output layer of the generator uses a sigmoid activation function, which constrains the output to the range (0, 1). This range is inappropriate for data that is meant to emulate a normal distribution with a mean of (0, 0), which would have values extending below 0 and above 1.

To correct this, the activation function of the generator's output layer should be changed. A normal distribution can take on values across the entire range of real numbers, so the activation function at the output layer should not artificially constrain this range. By changing the activation function to linear, the output can span all real values, allowing the generator to produce data that more closely resembles a normal distribution.

Additionally, the import statement for the ReLU activation function was incorrect. In recent versions of Keras, which is now a part of TensorFlow, ReLU should be imported from `tensorflow.keras.layers` directly. The ReLU activation function is used in the discriminator model to introduce non-linearity, which is appropriate for distinguishing between the real and fake data. The ReLU function is well-suited for this purpose because it helps to avoid the vanishing gradient problem, which can occur during the training of deep neural networks.

- g) Create an animation of the generated data over the course of the training process (with the real data plotted in a different color for reference). (15points)

```

[21]: import numpy as np
import matplotlib.pyplot as plt
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import Dense, ReLU
from matplotlib.animation import FuncAnimation
from IPython.display import HTML

```

```

# Set random seed for reproducibility
np.random.seed(0)
